PROCESS FOR PACKAGING AND SECURITIZING

FUTURE CRUDE OIL AND NATURAL GAS PRODUCTION STREAMS

3/5/2002

"Clean Form"

Amended Application

BACKGROUND OF THE INVENTION

(a) Field of the Invention

This invention relates to the securitization of future production streams and more particularly, but not by way of limitation, to a process for the securitization of future oil and natural gas production streams from one or more wells.

(b) Discussion of Prior Art

In the United States, there are roughly 2 billion barrels of oil and 12 trillion cubic feet of natural gas produced annually. Worldwide, there are roughly 23 billion barrels of oil and 30 trillion cubic feet of natural gas produced annually. This production translates into a stream of annual revenue, which can be made predictable when properly risk managed and insured, of over \$100 billion and \$500 billion in the United States and worldwide respectively. With the right data management tools and appropriate risk management techniques some of this revenue could potentially be packaged and securitized. Accordingly, the packaging and securitizing of this revenue stream presents a very large financial opportunity waiting to be exploited. With the recent development of systems for energy asset management used in managing very large volumes of oil and gas production data, it is now possible to realize the financial opportunity described herein.

Heretofore, oil and gas producers, especially smaller producers, producers with high debt/equity ratios and those working outside the United States, as well as the governments of many oil producing countries, currently have limited options as to

financing their field development, monetizing their assets or risk managing their production. The subject securitization process will greatly broaden oil and gas producers financing and risk management capabilities.

In U.S. Patent 5,806,048 to Kiron et al., a mutual fund securitization process is described. The securitization process is designed to allow the trading of open end mutual funds on or off the floor of a National Security Exchange. In U.S. Patent 5,812,988 to Sandretto, a method and system for imputing economic variables and estimating financial statements, future asset values, risks, etc is disclosed. In U.S. Patent 5,987,435 to Weiss to al., a data processing system is described for managing and implementing a form of security called "Proxy Asset". In U.S. Patent 6,112,188 to Hartnett, a method of using advanced communications of financial market trading for developing and implementing economic policies is described.

None of these prior art patents specifically disclose or teach the unique features, objects and advantages of the subject process for the securitization of future crude oil and natural gas production.

SUMMARY OF THE INVENTION

In view of the foregoing, it is a primary objective of the subject invention to provide a process for packaging and securitizing future oil and gas production streams from one or more wells. This process creates a new way in which oil and gas producing companies and governments of oil and gas producing countries can access financial markets. Also, the new process provides an oil and gas producer with greatly broadened financing and risk management capabilities.

Another object of the invention is to create a new "production backed security" based on current and future oil and gas production. The new security can be sold to investors with various degrees of risk and rate of return on the investment.

Still another object of the new securitizing process is the security based on the relative predictability of future oil and gas production levels over a certain period of time.

Yet another object of the invention is that the production backed security can be enhanced by hedging the commodity prices. The hedging of the prices helps reduce the risk to an investor as to future price fluctuations of oil and gas.

A further object of the process is that through the use of a finance or insurance company, the production backed security can be insured or guaranteed.

Another object of the new security process is that a security rating agency can be used to rate the production backed security based on fluctuations in price, political, governmental and geographical risks related to the operation of the wells and the location and geology of the oil and gas production.

The packaging and securitization process includes the step of establishing a trust or any other special purpose entity managed by a trustee or a fund manager. The trust is used for purchasing an oil and gas production stream from an oil and gas producer. A comprehensive database related to the oil and gas wells and their production is developed. The database is used for analyzing and then monitoring the oil and gas production stream to be purchased from the oil and gas producer. The trust issues and sells the production backed securities to investors. The trust pays the oil and gas producer from a portion of the proceeds from the sale of the security.

The process can also include hedging the price of the commodity using a commodity price hedge. The hedging helps reduce the risk related to future price fluctuations of oil and gas. Further, the process can include a guaranteed rate of return of the security to the investor by using credit enhancements and security insurance. Still further, a security rating agency can be used to rate the production backed security based on fluctuations in price, political, governmental and geographical risks related to the operation of the wells and the location and geology of the oil and gas production.

These and other objects of the present invention will become apparent to those familiar with different types of financial securities and the selling of crude oil and natural gas production when reviewing the following detailed description, showing novel construction, combination, and elements as herein described, and more particularly defined by the claims, it being understood that changes in the embodiments to the herein disclosed invention are meant to be included as coming within the scope of the claims, except insofar as they may be precluded by the prior art.

BRIEF DESCRIPTION OF THE DRAWINGS

The accompanying drawings illustrate complete preferred embodiments in the present invention according to the best modes presently devised for the practical application of the principles thereof, and in which:

FIG. 1 is a block diagram illustrating the individual components of creating the new “production backed security” and the steps used in packaging and securitizing the oil and gas product streams from one or more wells. FIG. 1 also includes optional components that can be used with different forms of the new security.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

In FIG. 1, a block diagram is shown of the individual components used in making up the process related to the new "production backed security" along with optional components that may or may not be used with the new security. It should be mentioned that while one production backed security is described herein, there can be a number of different types of production backed securities securitized by production streams from different oil and gas producers located in various parts of the world. Also, there can be any number of investors purchasing the oil and gas production backed securities. The securities having various rates of interest to the investors depending on the nature of the risk involved.

The process includes the establishing of a trust 10, fund or other special purchase entity. The trust 10 is operated by a trustee 12 or fund owner operating under a trust management agreement, indicated by line 14. The trust 10 pays the trustee 12 a management fee, as indicated by line 16.

An oil and gas producer 18 is contacted and a standardized contract is offered to the oil and gas producer. The proposed contract includes, among other items, a list of required data from the producer 18 for each well being packaged into the security. The list of required data for each well may include ownership data (such as mineral ownership, leases, assignments, recordings, etc.), production histories (oil, gas, water, etc.), technical well data (logs, cores, tests, well designs, etc.) and operating data (LOE's, taxes, division orders, production sale, purchase records, etc.).

When the required data from the oil and gas producer 18 is received, petroleum engineering/data manager/administrator 20 is used to provide a well, production and land ownership analysis, as indicated by line 22, and perform standard ownership due diligence and accounting of the data. At this time, the engineering/data manager/administrator 20 may reformat all of the data, builds additional databases and loads the well production data into a data management system. The well production data is available for review by authorized users anywhere in the world and at anytime, as indicated by line 24.

The engineering/data manager/administrator 20 uses the data to produce a conservative future production "decline curve". The decline curve will be estimated for each well or package of wells from the same production area. The data manager/administrator 20 will then "haircut" or discount the decline curve by determining a conservative percentage of the resulting curve. The percentage of the decline curve, which may be in a range of 5 to 100%, will represent the production stream to be securitized. For example, if the oil and gas producer 18 has a current level of production at 10,000 barrels of oil per day with the wells located in the United States, the agreed upon percentage of the decline curve might be 50% over a 2 to 5 year period or longer. Obviously, the location of the wells, the amount of production in the field, the favorability of additional production in the area, the cost of production, etc., will all influence the agreed upon percent of the decline curve and the amount of production to be packaged and securitized.

Also, it should be mentioned that the oil and gas producer will be required to provide the engineering/data manager/administrator 20 with periodic information updates related to each well or package of wells that are part of the securitization program. The data

provided will be continually added to the data management system and cross-checked, so that there is always up to date information on each well in the package along with ongoing monitoring of the purchased oil and gas production stream.

Once the production stream is purchased by the trust 10, as indicated by line 26, the production backed security issued by the trust 10 is sold to one or more investors 28, as indicated by line 30. The proceeds, as indicated by line 32, from the investor 28 is paid to the trust 10. A percent of the proceeds is paid to the oil and gas producer, as indicated by line 34. As mentioned above, the subject process creates a new way in which oil and gas producing companies and governments of oil and gas producing countries can access financial markets.

Shown in FIG. 1, are the following optional components that can be used with different forms of the new process for creating the production backed security. A hedge service provider 38 may or may not, as indicated by a "Yes/No" box 36 be used. If it is determined that the future prices of oil and gas for a certain period may be unstable, then it may be elected to hedge the prices of oil and gas for that period of time. The cost of the hedge will be factored into the cost of the production backed security sold to the investor. But, in this example, the new security will be protected against unforeseen changes in the pricing of oil and gas and will have a higher rating.

Also, a rating agency 42 may or may not, as indicated by "Yes/No" box 40 be used for rating a particular production backed security.

Further, a Finance or Insurance Company 46, may or may not, as indicated by "Yes/No" box 44 be used for insuring or guaranteeing the production backed security. The credit enhancement, as indicated by line 48, will further raise the rating of the issued securities.

Still further, if the oil and gas producer 18 does not already have well insurance for the wells being securitized, such insurance can be requested, as indicated by "Yes/No" box 50, well insurance, as indicated by line 54, from an insurance provider 52.

As mentioned above, the new oil and gas production backed security may take on various forms with different rates of return for the investor 28. The following are examples of higher risk securities. One type of security might be a higher risk passthrough hedge instrument wherein the price of the commodity is not hedged. Should the price of oil and gas move upwardly while the investor owns this type of security, then obviously the value of the security will greatly increase. Also, the new security may be commodity specific. For example, the production stream that is securitized is based only on oil production or only on natural gas production. Further, the security may be area specific. For example, the production stream that is securitized is based on a particular oil field in the United States or a country in the Middle East. Still further, the new security may have an added risk and reward of including yet undrilled wells in a particular area to be developed. If the drilling is successful, then the value of the security is increased substantially. Yet another example is the securitization of a production stream in a country with political risk. If the political risk is diminished or removed by appropriate insurance, then the investor is rewarded by a security having greatly increased value.

From reviewing the above process for creating the subject production backed security, it can be appreciated by those familiar with financing various forms of oil and gas projects that the subject invention provides an oil and gas producer with improved and broadened financial and risk management capabilities.

While the invention has been particularly shown, described and illustrated in detail with reference to the preferred embodiments and modifications thereof, it should be understood by those skilled in the art that equivalent changes in form and detail may be made therein without departing from the true spirit and scope of the invention as claimed except as precluded by the prior art.
